

CS240 Algorithm Design and Analysis  
Spring 2023  
Problem Set 5

---

Due: 23:59, May 24, 2023

1. Submit your solutions to the course Blackboard.
2. If you want to submit a handwritten version, scan it clearly.
3. Late homeworks submitted within 24 hours of the due date will be marked down 25%. Homeworks submitted more than 24 hours after the due date will not be accepted unless there is a valid reason, such as a medical or family emergency.
4. You are required to follow ShanghaiTech's academic honesty policies. You are allowed to discuss problems with other students, but you must write up your solutions by yourselves. You are not allowed to copy materials from other students or from online or published resources. Violating academic honesty can result in serious penalties.

### Problem 1:

Suppose you want to estimate the fraction  $f$  of people who skateboard in ShanghaiTech. Assume that you can select a ShanghaiTech student uniformly at random and determine whether they skateboard. Also, assume you know a lower bound  $0 < a < f$ . Design a procedure for estimating  $f$  by some  $\hat{f}$  such that  $\Pr[|f - \hat{f}| > \varepsilon f] < \delta$ , for any choice of constants  $0 < a, \varepsilon, \delta < 1$ . What is the smallest number of residents you must query?

## Problem 2:

Suppose that there are  $n$  items which need to be placed in some bins. The capacity of each bin is 1. The volumes of the items may not be the same and all volumes are smaller than 1. We want to use the fewest number of bins to place all items. Design a 2-approximation algorithm to solve this problem.

### Problem 3:

Consider the following simple model of gambling in the presence of bad odds. At the beginning, your net profit is 0. You play for a sequence of  $n$  rounds. In each round, your net profit increases by 1 with probability  $1/3$ , and decreases by 1 with probability  $2/3$ . Show that the expected number of steps for which your net profit is positive can be upper-bounded by an absolute constant, independent of the value of  $n$ .

## Problem 4:

Given a set of items, where the  $i$ 'th item has size  $c_i$  ( $c_i > 0$ ), we want to place them in as few bins as possible. Each bin has a capacity  $V$ , where  $V \geq \max_i c_i$ . To try to minimize the number of bins used, we take the following steps. We start with one active bin, then iterate through the items one by one and try to place the item into any active bin which can accommodate it. If an item cannot fit into any active bin, we open a new active bin. The algorithm is shown below. Prove that this algorithm is a 2-approximation, i.e. the number of bins it uses is at most twice the minimum possible number of bins required.

### Algorithm:

---

**Input** : Set of items with sizes  $c_1, c_2, \dots, c_n$

**Output:** Number of bins used

Sort the items in non-decreasing order of their sizes:  $c_1 \leq c_2 \leq \dots \leq c_n$

**for**  $i \leftarrow 1$  **to**  $n$  **do**

**for**  $j \leftarrow 1$  **to**  $k$  **do**

**if** *item  $i$  fits into active bin  $j$*  **then**

            place item  $i$  in bin  $j$

            break

**end**

**end**

**else**

        open a new active bin  $k + 1$

$k \leftarrow k + 1$

        place item  $i$  in bin  $k + 1$ ;

**end**

**end**

**return** *number of active bins  $k$*

---

### Problem 5:

Suppose that for some decision problem, we have an algorithm which on any instance computes the correct answer with probability at least  $4/5$ . We wish to reduce the probability of error by running the algorithm  $n$  times on the same input using independent randomness between trials and taking the most common result. Using Chernoff bounds, give an upper bound on the probability that this new algorithm produces an incorrect result.
